15 **ABSTRACT**

16 The present work focuses on the photo-catalytic degradation of methyl orange (MO) on  
17 Erbium trioxide nanoparticles "Er<sub>2</sub>O<sub>3</sub> NPs". In this study, Er<sub>2</sub>O<sub>3</sub> nanoparticles were  
18 synthesized and fully characterized via various techniques including; XRD diffraction, UV-  
19 Vis spectroscopy and SEM techniques. The results revealed that, the photo-catalytic activity  
20 of the prepared Er<sub>2</sub>O<sub>3</sub> NPs towards methyl orange (MB) photo-degradation was manifested.  
21 The optimum efficiency obtained was 16%.

22  
23 **Keywords:** methyl orange; Er<sub>2</sub>O<sub>3</sub>; Photo-catalytic; XRD; SEM Nomenclature

24 **1 Introduction**

25 One of the sources of water contamination was the wastewater generated from textile-plants  
26 employing various dyestuffs (Khataee and Kasiri, 2010; Barbe et al., 1997). Various chemical  
27 and physical in addition to biological changes for dyes could occur that consume dissolved  
28 oxygen in the water bodies. Moreover, dyes have high toxicity which endangers aquatic life  
29 (Khataee et al., 2009; Ruiz et al., 2004). The various traditional techniques employed for the  
30 processing of pollutants textile dyes in water involve different chemical, biological and/or  
31 physical techniques. Photo-catalytic degradation was demonstrate as a promising technique for  
32 processing of pollutions that occur due to organic and/or inorganic compounds. The approach,

33 as a means of removal of persistent water contaminants like dyes and pesticides was attracted  
 34 recently the attention of numerous investigators (Xu et al., 2014; Chen et al., 2014; Liu et al.,  
 35 2014). Considerable of these researchers were used suspension (aqueous) of semi-conductors  
 36 irradiated by UV-light to photo-degrade the pollutants (Daneshvar et al., 2007). The  
 37 accomplishment of a semi-conductor photo-catalyst was strongly connected with the electronic  
 38 structure of it (Daneshvar et al., 2007; Boppella et al., 2013; Xiao et al., 2012; Alenezi et al.,  
 39 2013). It was established that the photo-catalytic degradation of organic ions or organic  
 40 molecules in solution are launched by photo-generated holes in valence band with electrons in  
 41 the conduction band of the semi-conductor photo-catalyst. The generated holes have high  
 42 oxidative potential that permits a direct oxidation of organic ions or organic molecules to  
 43 reactive intermediates. Moreover, radicals are reactive species that may help in organic  
 44 substrate degradation. Methyl orange as in Fig. 1, is a scale of acidity utilized in titration due  
 45 to its clear and distinct color difference at various pH values. Methyl orange demonstrates pink  
 46 colour in acidic solution and yellow colour in basic solution. Due to it variations colour at the  
 47 pH of a mid-strength acid, it is ordinarily utilized in titration for acid solutions. Unlike a global  
 48 indicator, methyl orange does not have a full spectrum of colour variation, but it has a sharp  
 49 end (Khodja et al., 2001; Sandberg et al., 1972).

50

51

Fig. 1

52

53 Generally, MO utilized monoazo dye in laboratory tests, textiles and different commercial  
 54 products and has to be eliminate from water because of its toxicity (Mittal et al., 2007; Chen et  
 55 al., 2010). Mittal et al. (Mittal et al., 2007) searched the eliminate and recovery of MO from  
 56 wastewaters employing waste materials. Chen and his co-workers (Chen et al., 2010) examined  
 57 the equilibrium and kinetic aspects of MO adsorption on activated carbon derived from  
 58 Phragmites australis. Jiang and other researchers (Jiang et al., 2012) investigated the removal  
 59 of MO from solutions through Maghemite-Chitosan NPs. Therefore, there is a need to develop  
 60 a novel treatment method that is more effective in eliminating dyes from the wastewater. The  
 61 objective and novelty of the present work is to study the factors effecting on photo-catalytic oxidation  
 62 process of methyl orange dye using the synthesized erbium trioxide Nanoparticles such as  
 63 concentration, illumination time and amount of catalyst loaded used in photo-catalytic process. In  
 64 this investigation, we searched the photo-catalytic degradation of MO on Er<sub>2</sub>O<sub>3</sub> NPs.

65

66

## 67 2 Experimental

### 68 2.1 Materials

69 All materials used in this work were supplied from Fluka Company, and were used without  
70 further purification.

### 71 2.2 Synthesis of Er<sub>2</sub>O<sub>3</sub> NPs

72 Erbium oxide nanoparticles (Er<sub>2</sub>O<sub>3</sub> NPs) had been synthesized by dissolving of ascorbic acid  
73 (1 g) and of sodium fluoride (0.063 g) in distilled water (10 mL). Adjusted the pH solution to  
74 four by adding drops of ammonium hydroxide solution. The resulting solution was heated to  
75 70 °C for 20 min. An alcoholic solution of Erbium nitrate (2.5 g in 4 mL) had been added to  
76 the above solution and continuous stirring 2 hr. At room temperature. Centrifuged and washed  
77 the precipitate several times with de-ionized water dried in air for 24 hr under vacuum. The  
78 precipitate, then calcinated at 800 °C for 3 hr.

### 79 2.3 Sample Preparation

80 Er<sub>2</sub>O<sub>3</sub> nanoparticles were prepared as the catalyst of 0.1 g diluted in 100 mL methanol). Erbium  
81 oxide Er<sub>2</sub>O<sub>3</sub> and methyl orange (MO) were weighed by using sensitive balance. MO as a dye  
82 often used for catalytic tests (0.05 g diluted with 500 mL methanol).

### 83 2.4 Photo-Catalytic Setup

84 The photo-catalytic set-up consists of UV- source as a lamp (6 watt) of cylindrical shape 22  
85 cm body length and 16 cm arc length of cylindrical shape, which was used as a photo source.  
86 This was used as a photo source. This lamp was positioned in a container of the sample (mixture  
87 of Er<sub>2</sub>O<sub>3</sub> NPs and MO) and then placed on magnetic stirrer (to mix and disperse solutions result  
88 of high speeds and long time to prepare it solutions) (Chen et al., 2014).

### 89 2.5 Methods

#### 90 2.5.1 Irradiation Time Effect

91 The Mixture of Er<sub>2</sub>O<sub>3</sub> NPs and MO was placed on magnetic stirrer and the temperature was  
92 fixed at 25 °C. The UV-lamp was switched on inside the sample container. Different irradiation  
93 time (1, 2, 3, 4 and 5 hr) were employed. The photo degradation measured after each hour. The  
94 samples were examined by UV-spectrometer to measure the absorbance of all sample.

#### 95 2.5.2 Dye Concentration Effect

96 Different concentrations of the MO were used in the range of (0.1, 0.2, 0.5, 1, 1.5, 2) wt.% and  
97 0.1 wt.% from Er<sub>2</sub>O<sub>3</sub> NPs. The samples withdrawn from the mixture without photo catalysts  
98 and after 15 minute for each concentration of MO. The samples were examined by UV-visible  
99 spectrophotometer to measure the optical absorbance.

#### 100 2.5.3 Scanning Electron Microscopy (SEM)

101 The morphology of the nanoparticles of Erbium oxide nanoparticles was studied by SEM. It  
102 was recorded on the JEOL JSM-6390LV SEM fitted with secondary electron detector.

#### 103 2.5.4 X-ray diffraction (XRD)

104 The crystallinity of Er<sub>2</sub>O<sub>3</sub> powder was studied by X-ray diffraction (XRD) technique.

### 105 3 Results and Discussion

106 To improve the photo-degradation efficiency of methyl orange dye, erbium trioxide nanoparticles  
107 were used as a common strategy. Erbium trioxide nanoparticles were ready to synthesis and cheap.  
108 Various types of nano-metal have been used in the previous studies, including anionic dopants,  
109 cationic dopants, rare-earth dopants, and codopants ( Samadi et al., 2014). Besides, many studies  
110 have shown that coupling with other semiconductors, such as CdO ( Liu et al., 2014), CeO<sub>2</sub> ( Uddin  
111 et al., 2012)], SnO<sub>2</sub>,TiO<sub>2</sub> ( Pant et al., 2012), graphene oxide (GO) ( Dai et al., 2014), and reduced  
112 grapheme oxide (RGO) ( Zhou et al., 2012), is a feasible approach to enhance the photodegradation  
113 efficiency.

#### 114 3.1 Absences of Sunlight

115 The results had been discussed with/without sunlight as shown in Figs. 2 and 3. Fig. 2  
116 demonstrates the relation between absorbance and time of photo-catalytic without sunlight  
117 radiation. The increasing of time of photo-degradation up to 3.0 hr, leads to that the absorbance  
118 values will raise, due to the degradation process organic dye. This attitude harmonize with  
119 Lazar et al. (Lazar et al., 2012). Fig. 3 elucidate the absorption of Er<sub>2</sub>O<sub>3</sub> spectrum in absence  
120 of sun light (SL), that could be shown that the minimum absorption occur at wavelength range  
121 of (324-489 nm) for various irradiative time.

122

123

124

Fig. 2

125 Fig. 3 shows the absorption spectrum of Er<sub>2</sub>O<sub>3</sub> nanoparticles without SL. One can be  
126 shown that the minimum absorption take place at the range of wavelength (450-600 nm) for  
127 different irradiative time. A transmission spectrum has maximum intensities at wavelengths  
128 where the absorption is weakest because more light is transmitted through the sample. An

129 absorption spectrum has maximum intensities at wavelengths where the absorption is strongest.  
130 When sample molecules are exposed to light having an energy that matches a possible  
131 electronic transition within the molecule, some of the light energy will be absorbed as the  
132 electron is promoted to a higher energy orbital. An optical spectrometer records the  
133 wavelengths at which absorption occurs, together with the degree of absorption at each  
134 wavelength. Absorbance usually ranges from 0 to 3.5, and is precisely defined in context with  
135 spectrometer operation.

136

137

Fig. 3

138 3.2 In presence of SL

139 Fig. 4 shows the photo-catalytic degradation of diazocompounds irradiated under sunlight in  
140 the presence of  $\text{Er}_2\text{O}_3$  nanoparticles. The presence of  $\text{Er}_2\text{O}_3$  nanoparticles was investigated as  
141 a very important factor for improvement the degradation process. Higher efficiency of  
142 degradation was found within 4.0 hr, of irradiation time and considering the optimum loading  
143 of catalyst. After 4.0 hr, of irradiation time with  $\text{Er}_2\text{O}_3$  nanoparticles, can be shown other peak  
144 at irradiation time of 5.0 hr, when we carried out a comparison between the absorbance values  
145 at 5 hr. with Fig. 2 and without sunlight can be conclude the improvement in phenolic  
146 compound degradation when taken into account the role of sunlight.

147

148

Fig. 4

149

150 The rate of reaction increases and maximum rates were getting after four hour as shown in  
151 Fig. 5. It may be explained on the basis that the operation time of UV source was increased,  
152 the number of photons per unit area incident on the sample also increased, resulting in high  
153 rate of degradation in the mixture of Erbium oxide and MO Leads to increase the absorption  
154 value.

155

156

Fig. 5

157 3.3 Impact of Methylene Blue Concentration

158 3.3.1 Concentration of MO Effects without Irradiation

159 The increasing in the dye concentration leads to increases of absorbance. The maximum change  
160 of absorbance increasing was noticed when the concentration changed from 0.5 wt.% to 1 wt.%

161 as shown in Fig. 6. The degradation efficiency of MO was analyzed using UV-Vis  
162 spectrometer. Peaks were observed to be present between 450 and 600 nm, which was  
163 indicative of the degradation of MO. According to Beer-Lambert Law, MO concentration is  
164 directly proportional to its absorbance (Ramli et al., 2014).

### 165 3.3.2 Concentration of MO Effects with Irradiation

166 When MO concentration increased leads to the value of absorbance was increased after 15 min  
167 from irradiation. Maximum increasing in absorbance notice when changed the concentration  
168 at the period (0.5-1.0) wt.% as shown in Fig. 6. This might be elucidated base on the increasing  
169 of dye concentrations that leads to the reaction average increases as additional, molecules.  
170 When increased the dye (3.0-5.0) wt.% the value of absorbance remains constant at 4.51 wt.%  
171 cause reaction retardation because of the increasing in number of collisions between dye  
172 molecules whereas, collisions between dye and salt decrease. As a conclusion, proportion of  
173 reaction was decrease (Karunakaran et al., 2004; Pandey et al., 2015). The main rate of  
174 degradation exists in the region near irradiated side where the intensity of irradiation was much  
175 higher than in the other sides. Thus, dye with higher concentration, the degradation technique  
176 decreases at sufficiently long distances from the light source or the reaction zone because of  
177 retardation in the penetration of light.

178

179 Fig. 6

### 180 3.4 SEM Results

181 The SEM micrographs of synthesized samples are shown in Figs. 7, 8, 9 and 10, this Figs. show  
182 the distribution and the morphology of Er<sub>2</sub>O<sub>3</sub> nanoparticles. The average size of the  
183 nanoparticles was found to be (~16 nm) and appeared to be uniform.

184

185 Fig. 7

186

187 Fig. 8

188

189 Fig. 9

190

191 Fig. 10

### 192 3.5 XRD Results

193 XRD was used to clarify the  $\text{Er}_2\text{O}_3$  nanoparticles phase formation. All the reflections were well  
194 indexed to cubic phase of  $\text{Er}_2\text{O}_3$  nanoparticles and can be seen from Fig. 11, XRD parameter  
195 of  $\text{Er}_2\text{O}_3$  nanoparticles show in Table 1 with a space group of  $I 21 3 (199)$  and cell parameters  
196 of  $a=10.5400 \text{ \AA}$ . The excellent crystallinity and absence of impurities can be inferred because  
197 of sharpness and exact number of peaks in the XRD pattern. Additionally, it indicates that the  
198 product is a single phase. XRD was used to clarify the  $\text{Er}_2\text{O}_3$  nanoparticles phase formation.  
199 All the reflections were well indexed to cubic phase of  $\text{Er}_2\text{O}_3$  nanoparticles, the average  
200 crystallite size of  $\text{Er}_2\text{O}_3$  nanoparticles is found to be 16 nm.

201

202 Fig. 11

203 Table 1

204

### 205 4 Conclusion

206 Nanoparticles of  $\text{Er}_2\text{O}_3$  under SL improvement the effectiveness degradation diazomium  
207 compounds for methyl orange or in other words removal of mixture polluted by methyl orange.  
208 The photo catalytic activity under UV and light illumination, components for the enhanced  
209 photo synergist reactivity of the  $\text{Er}_2\text{O}_3$ . The  $\text{Er}_2\text{O}_3$  nanoparticles have stage and it is ready to  
210 ingest a high measure of photo catalytic in the obvious light area, driving adequately  
211 photochemical degradation responses. Maximum increasing of absorbance was noticed when  
212 the concentration of MO increased from 0.5 wt.% to 1wt.% and this behavior leads to  
213 increasing degradation of MO up to 14 % for  $\text{Er}_2\text{O}_3$  catalyst. XRD measurements show that the  
214 structure of  $\text{Er}_2\text{O}_3$  nanoparticles was Cubic, the average crystallite size of  $\text{Er}_2\text{O}_3$  nanoparticles  
215 is found to be 16 nm.
